ABSTRACT

M. Gjorgjiev and D Petkovski (1994). Content of total and easy soluble cobalt in the vertisols of Kratovo-Zletovo volcanic region. *Ekol Zast. Život. Sred.*, Vol. 2, No. 2, Skopje.

The paper represents the investigations on total and easy soluble cobalt content in the vertisols of Kratovo-Zletovo volcanic region.

The content of the total cobalt is 3,00 to 18,00 ppm. The soils of profile 734 and 720 have the highest content of total cobalt, while of profile 15,727 and 7 have the lowest one. The contents of an easily soluble and total Co and pH, and the content of carbonates direct relation is not noticed.

Key words: Volcanic vertisols, total and soluble cobalt content.

ИЗВОД

Горѓиев, М. и Петковски, Д. (1994). Содржината на вкупен и лесно растворлив кобалт во смол-ниците на кратовско-злетовскиот вулкански регион. *Екол. Зашт. Живот. Сред.*, Том 2, Бр. 2, Скопје.,

Трудот ги презентира истражувањата на содржината на вкупниот и лесно растворлив кобалт во смолниците на кратовско-злетовскиот вулкански регион.

Содржината на вкупниот кобалт се движи во границите од 3,00 до 18,00 ppm. Истражуваните почви содржат доволно лесно растворлив кобалт за исхрана на растенијата. Зависност помеѓу содржината на лесно растворлив кобалт и pH реакцијата на почвата, како и со содржината на карбонатите не беше воспоставена. Намалувањето на содржината на хумусот во почвениот профил го условува намалувањето на содржината на кобалт.

Клучни зборови: Вулкански смолници, вкупен и растворлив кобалт.

INTRODUCTION

In practice, cobalt is of less significance for the vegetable than for the animal nourishment. It is known that the cobalt as a metal component of vitamin B12 is required for the animal nitrogen metabolism. Insufficient contents of Co in the fodder can lead in some cases to a deficiency of Co with the ruminants. According to Mitchell (1945), in case the Co content in the fodder is less than 0,08 ppm Co in the dry substance some signs of a deficit appear with the sheep.

According to Henkens (1965) soil contents of 0,1 ppm (extract of acetic acid) is not sufficient for obtaining fodder with the necessary content of Co for the animal feeding.

Having in mind the above mentioned and taking into consideration that the supply with an easily soluble cobalt has been investigated so far only in some soils of low-hills and mountain pastures (Gjorgjiev and Jekić 1970) and on cinamonic forest soils in Macedonia (Spirovski and Gjorgjiev 1971), in 1993 the content

of the total and easily soluble cobalt in the vertisols of Kratovo - Zletovo volcanic area was

investigated, and the results obtained are presented herein.

MATERIAL AND METHODS

The soil samples of the chosen vertisols localities are presented in Tab. 1 and Tab. 2.

The mechanical composition of the soils was determined by the pipette method (Resulović 1971), the reaction (pH - value) by the electrometric analysis, the carbonates by Schreibler calcimeter and the humus - on the basis

of ther total carbon according Grišin 1981, Smakov 1957). The content of the total cobalt in the soils was extracted with 10% hydrochloric acid (Scharrer and Taubel 1955) and for the easily soluble cobalt with buffered n solution of acetic acid (Baron 1954) and was determined by Perkins - Elmer atomic spectral-photometer.

RESULTS AND DISCUSSION

The investigated vertisols of Rratovo - Zletovo volcanic area (Tab. 1) according to the mechanical composition are heavy soils because they contain over 35% colloidal clay. According to the obtained results, the vertisols formed on the andezite breccias (profile 11 and 743 with colloidal clay over 50%) are the heaviest ones.

The humus percentage in the superficial horizons is an average and a high one, whereas when deepening, in most of the profiles it decreases.

In respect of the carbonates content, the soils are noncalcareous and weakly calcareous in the superficial horizons while in the deeper horizons, from noncalcareous to considerably calcareous ones.

Depending on the carbonates quantities the reaction of the soils varies from acid to weakly basic one.

The results on Tab. 2 show that the vertisols of Kratovo - Zletovo eruptive region contain enough cobalt for plaht nourishment (according to the experiments, 0,5 ppm soluble Co in 0,5 acetic acid is enough in Holland, while in Scotland, the researches show 0,25 ppm Co). The decreasing of the humus content along the profile depth decreases its content, too. The vertisols of profile 74.3 contain the highest content of easily soluble Co, while the lowest on is of profile 727.

According to the Baron's data (1954) the content of easily soluble Co in soils varies considerably and are of 0,50 to 6,00 ppm. The sandy soils have small quantities of Co, as well as the low land marshy soils and the soils formed by weathering of the primitive rocks

on a granite basis. The cobalt content is most often here under 0,2 ppm. On the contrary, the clay soils, especially the soils formed by weathering of basalt and the salt soils are considerably rich in cobalt (to 6 ppm). In this respects our results are in accordance with Baron's data (1954).

The highest content of total Co have the soils of profile 734 (formed on paleogenetic sediments) and 720 (formed by proluvium on paleogenetic sediments) while the lowest one is of profile 15 (formed on hornblende - augite -biotite - andesite), 727 and 7 (formed on andesite tuffs).

Direct relation among the contents of an easily soluble and total Co and pH - value, and the content of the carbonates, is not noticed. That is the reason that we did not present these results in this article.

The soils may have a lot of different quantities of total cobalt (Mengel 1968). According to Hill et all. (1953) the content of total Co in soils varies between 0,2 and 31 ppm. However, Co is mainly built - in crystal grating of separate minerals. Similary as with the Cu the concentration of Co in the soil solution is also extrimely low. The available Co for the plants is mainly sorptively bound to the. soil colloides.

The vertisols of Kratovo - Zletovo volcanic area compared to some soils of low - hills and mountainous pastures in Macedonia (Gjorgjiev and Jekić 1970) are better supplied while, compared with the cinnamonic forest soils in Macedonia (Spirovski and Gjorgjiev 1971) contain less concentrations of espy soluble Co for plants nourishment.

СОДРЖИНА НА ВКУПЕН И ЛЕСНО РАСТВОРЛИВ КОБАЛТ ВО СМОЛНИЦИТЕ НА КРАТОВСКО – ЗЛЕТОВСКИОТ ВУЛКАНСКИ РЕГИОН

Митко ГОРЃИЕВ¹ и Диме ПЕТКОВСКИ²

¹ Институт за биологија, ПМФ, Скопје 91000, Македонија

² Институт за земјоделство, Педолошки оддел, Скопје 91000, Македонија

РЕЗИМЕ

Истражувањата на содржината на вкупен и лесно растворлив кобалт во смолниците на Кратовско - Злетовскиот вулкански регион ги дадоа овие резултати:

Почвите се снабдени со доволно лесно растворлив кобалт за исхрана на растенијата. Со намалување содржината на хумус по длабочина на профилот се намалува неговата содржина. Највисока содржина лесно растворлив Со има смолницата на профилот 743 додека најниска на профилот 727.

Содржината на вкупен кобалт изнесува од 3,00 до 18,00 ррм. Најголема содржина вкупен Со содржат почвите на профилот 743 додека најмала на профилот 15,727 и 7.

Меѓу содржините на лесно растворлив и вкупен Со и pH односот содржината на карбонати не се приметува директен однос.
